**Notes**
Carl Linnaeus (Lua error in package.lua at line 80: module 'Module:IPAc-en/data' not found.;[1] 23 May[note 1] 1707 – 10 January 1778), also known after his ennoblement as Carl von Linné[2] (Template:IPA-sv), was a Swedish botanist, physician, and zoologist, who laid the foundations for the modern biological naming scheme of binomial nomenclature. He is known as the father of modern taxonomy, and is also considered one of the fathers of modern ecology. Many of his writings were in Latin, and his name is rendered in Latin as Lua error in package.lua at line 80: module 'Module:Exponential search' not found. (after 1761 Carolus a Linné).

Linnaeus was born in the countryside of Småland, in southern Sweden. He received most of his higher education at Uppsala University, and began giving lectures in botany there in 1730. He lived abroad between 1735 and 1738, where he studied and also published a first edition of his Lua error in package.lua at line 80: module 'Module:Exponential search' not found. in the Netherlands. He then returned to Sweden, where he became professor of medicine and botany at Uppsala. In the 1740s, he was sent on several journeys through Sweden to find and classify plants and animals. In the 1750s and '60s, he continued to collect and classify animals, plants, and minerals, and published several volumes. At the time of his death, he was one of the most acclaimed scientists in Europe.

The Swiss philosopher Jean-Jacques Rousseau sent him the message: "Tell him I know no greater man on earth."[3] The German writer Johann Wolfgang von Goethe wrote: "With the exception of Shakespeare and Spinoza, I know no one among the no longer living who has influenced me more strongly."[3] Swedish author August Strindberg wrote: "Linnaeus was in reality a poet who happened to become a naturalist".[4] Among other compliments, Linnaeus has been called Lua error in package.lua at line 80: module 'Module:Exponential search' not found. (Prince of Botanists), "The Pliny of the North," and "The Second Adam".[5] American news agency Time named Linnaeus the 31st most influential person in human history and the 5th most influential scientist.[6]

In botany, the author abbreviation used to indicate Linnaeus as the authority for species' names is L.[7] In older publications, sometimes the abbreviation "Linn." is found (for instance in: Cheeseman, T.F. (1906) – Manual of the New Zealand Flora). Linnaeus' remains comprise the type specimen for the species Homo sapiens, following the International Code of Zoological Nomenclature, since the sole specimen he is known to have examined when writing the species description was himself.[note 2]
Carl Linnaeus was born in the village of Råshult in Småland, Sweden, on 23 May 1707. He was the first child of Nils Ingemarsson Linnaeus and Christina Brodersonia. His father was the first in his ancestry to adopt a permanent surname. Before that, ancestors had used the patronymic naming system of Scandinavian countries: his father was named Ingemarsson after his father Ingemar Bengtsson. When Nils was admitted to the University of Lund, he had to take on a family name. He adopted the Latin name Linnaeus after a giant linden tree (or lime tree), in Swedish, that grew on the family homestead. This name was spelled with the æ ligature. When Carl was born, he was named Carl Linnaeus, with his father's family name. The son also always spelled it with the æ ligature, both in handwritten documents and in publications. Carl's patronymic would have been Nilsson, as in Carl Nilsson Linnaeus.

One of a long line of peasants and priests, Nils was an amateur botanist, a Lutheran minister, and the curate of the small village of Stenbrohult in Småland. Christina was the daughter of the rector of Stenbrohult, Samuel Brodersonius. She subsequently gave birth to three daughters and another son, Samuel (who would eventually succeed their father as rector of Stenbrohult and write a manual on beekeeping). A year after Linnaeus' birth, his grandfather Samuel Brodersonius died, and his father Nils became the rector of Stenbrohult. The family moved into the rectory from the curate's house.

Even in his early years, Linnaeus seemed to have a liking for plants, flowers in particular. Whenever he was upset, he was given a flower, which immediately calmed him. Nils spent much time in his garden and often showed flowers to Linnaeus and told him their names. Soon Linnaeus was given his own patch of earth where he could grow plants.

**Early education**

Linnaeus' father began teaching him Latin, religion, and geography at an early age; one account says that due to family use of Latin for conversation, the boy learned Latin before he learned Swedish. When Linnaeus was seven, Nils decided to hire a tutor for him. The parents picked Johan Telander, a son of a local yeoman. Linnaeus did not like him, writing in his autobiography that Telander "was better calculated to extinguish a child's talents than develop them." Two years after his tutoring had begun, he was sent to the Lower Grammar School at Växjö in 1717. Linnaeus rarely studied,
often going to the countryside to look for plants. He reached the last year of the Lower School when he was fifteen, which was taught by the headmaster, Daniel Lannerus, who was interested in botany. Lannerus noticed Linnaeus’ interest in botany and gave him the run of his garden. He also introduced him to Johan Rothman, the state doctor of Småland and a teacher at Katedralskolan (a gymnasium) in Växjö. Also a botanist, Rothman broadened Linnaeus’ interest in botany and helped him develop an interest in medicine. At the age of 17, Linnaeus had become well acquainted with the existing botanical literature. He remarks in his journal “read day and night, knowing like the back of my hand, Arvidh Månsson’s Rydaholm Book of Herbs, Tillandz’s Flora Åboensis, Palmberg's Serta Florea Suecana, Bromelii Chloros Gothica and Rudbeckii Hortus Upsaliensis....”

Linnaeus entered the Växjö Katedralskola in 1724, where he studied mainly Greek, Hebrew, theology and mathematics, a curriculum designed for boys preparing for the priesthood. In the last year at the gymnasium, Linnaeus' father visited to ask the professors how his son's studies were progressing; to his dismay, most said that the boy would never become a scholar. Rothman believed otherwise, suggesting Linnaeus could have a future in medicine. The doctor offered to have Linnaeus live with his family in Växjö and to teach him physiology and botany. Nils accepted this offer.

University studies

Lund

Rothman showed Linnaeus that botany was a serious subject. He taught Linnaeus to classify plants according to Tournefort's system. Linnaeus was also taught about the sexual reproduction of plants, according to Sébastien Vaillant. In 1727, Linnaeus, age 21, enrolled in Lund University in Skåne. He was registered as Lua error in package.lua at line 80: module 'Module:Exponential search' not found., the Latin form of his full name, which he also used later for his Latin publications.

Professor Kilian Stobæus, natural scientist, physician and historian, offered Linnaeus tutoring and lodging, as well as the use of his library, which included many books about botany. He also gave the student free admission to his lectures. In his spare time, Linnaeus explored the flora of Skåne, together with students sharing the same interests.

Uppsala

In August 1728, Linnaeus decided to attend Uppsala University on the advice of Rothman, who believed it would be a better choice if Linnaeus wanted to study both medicine and botany. Rothman based this recommendation on the two professors who taught at the medical faculty at Uppsala: Olof Rudbeck the Younger and Lars Roberg. Although Rudbeck and Roberg had undoubtedly been good professors, by then they were older and not so interested in teaching. Rudbeck no longer gave public lectures, and had others stand in for him. The botany, zoology, pharmacology and anatomy lectures were not in their best state. In Uppsala, Linnaeus met a new benefactor, Olof Celsius, who was a professor of theology and an amateur botanist. He received Linnaeus into his home and allowed him use of his library, which was one of the richest botanical libraries in Sweden.
In 1729, Linnaeus wrote a thesis, *Lue error in package.lua at line 80: module 'Module:Exponential search' not found.* on plant sexual reproduction. This attracted the attention of Rudbeck; in May 1730, he selected Linnaeus to give lectures at the University although the young man was only a second-year student. His lectures were popular, and Linnaeus often addressed an audience of 300 people.[31] In June, Linnaeus moved from Celsius' house to Rudbeck's to become the tutor of the three youngest of his 24 children. His friendship with Celsius did not wane and they continued their botanical expeditions.[32] Over that winter, Linnaeus began to doubt Tournefort's system of classification and decided to create one of his own. His plan was to divide the plants by the number of stamens and pistils. He began writing several books, which would later result in, for example, *Lue error in package.lua at line 80: module 'Module:Exponential search' not found.* and *Lue error in package.lua at line 80: module 'Module:Exponential search' not found.* He also produced a book on the plants grown in the Uppsala Botanical Garden, *Lue error in package.lua at line 80: module 'Module:Exponential search' not found.*[33]

Rudbeck's former assistant, Nils Rosén, returned to the University in March 1731 with a degree in medicine. Rosén started giving anatomy lectures and tried to take over Linnaeus' botany lectures, but Rudbeck prevented that. Until December, Rosén gave Linnaeus private tutoring in medicine. In December, Linnaeus had a "disagreement" with Rudbeck's wife and had to move out of his mentor's house; his relationship with Rudbeck did not appear to suffer. That Christmas, Linnaeus returned home to Stenbrohult to visit his parents for the first time in about three years. His mother had disapproved of his failing to become a priest, but she was pleased to learn he was teaching at the University.[33][34]

**Expedition to Lapland**

*Main articles: Expedition to Lapland and Flora Lapponica*

During a visit with his parents, Linnaeus told them about his plan to travel to Lapland; Rudbeck had made the journey in 1695, but the detailed results of his exploration were lost in a fire seven years afterwards. Linnaeus' hope was to find new plants, animals and possibly valuable minerals. He was also curious about the customs of the native Sami people, reindeer-herding nomads who wandered Scandinavia's vast tundras. In April 1732, Linnaeus was awarded a grant from the Royal Society of Sciences in Uppsala for his journey.[35][36]

Linnaeus began his expedition from Uppsala in May; he travelled on foot and horse, bringing with him his journal, botanical and ornithological manuscripts and sheets of paper for pressing plants. Near Gävle he found great quantities of *Campanula serpyllifolia*, later known as *Linnaea borealis*, the twinflower that would become his favourite.[37] He sometimes dismounted on the way to examine a flower or rock[38] and was particularly interested in mosses and lichens, the latter a main part of the diet of the reindeer, a common and economically important animal in Lapland.[39]

Linnaeus travelled clockwise around the coast of the Gulf of Bothnia, making major inland incursions from Umeå, Luleå and Tornio. He returned from his six-month-long, over 2,000 kilometres (1,200 mi) expedition in October, having gathered and observed many plants, birds and
Although Lapland was a region with limited biodiversity, Linnaeus described about 100 previously unidentified plants. These became the basis of his book Linnaeus in the traditional dress of the Sami people of Lapland, holding the twinflower, later known as Linnaea borealis, that became his personal emblem.

In Linnaeus' ideas about nomenclature and classification were first used in a practical way, making this the first proto-modern Flora. The account covered 534 species, used the Linnaean classification system and included, for the described species, geographical distribution and taxonomic notes. It was Augustin Pyramus de Candolle who attributed Linnaeus with Linnaeus' ideas about nomenclature and classification were first used in a practical way, making this the first proto-modern Flora. Botanical historian E. L. Greene described as "the most classic and delightful" of Linnaeus's works.

It was also during this expedition that Linnaeus had a flash of insight regarding the classification of mammals. Upon observing the lower jawbone of a horse at the side of a road he was traveling, Linnaeus remarked: "If I only knew how many teeth and of what kind every animal had, how many teats and where they were placed, I should perhaps be able to work out a perfectly natural system for the arrangement of all quadrupeds."

In 1734, Linnaeus led a small group of students to Dalarna. Funded by the Governor of Dalarna, the expedition was to catalogue known natural resources and discover new ones, but also to gather intelligence on Norwegian mining activities at Røros.

**Doctorate**

Back in Uppsala, Linnaeus' relations with Nils Rosén worsened, and thus he gladly accepted an invitation from the student Claes Sohberg to spend the Christmas holiday in Falun with Sohberg's family. Sohberg's father was a mining inspector, and let Linnaeus visit the mines near Falun. Sohland's father suggested to Linnaeus he should bring Sohberg to the Dutch Republic and continue to tutor him there for an annual salary. At that time, the Dutch Republic was one of the most revered places to study natural history and a common place for Swedes to take their doctoral degree; Linnaeus, who was interested in both of these, accepted.

In April 1735, Linnaeus and Sohberg set out for the Netherlands, with Linnaeus to take a doctoral degree in medicine at the University of Harderwijk. On the way, they stopped in Hamburg, where they met the mayor, who proudly showed them a wonder of nature which he possessed: the taxidermied remains of a seven-headed hydra. Linnaeus quickly discovered it was a fake: jaws and clawed feet from weasels and skins from snakes had been glued together. The provenance of the hydra suggested to Linnaeus it had been manufactured by monks to represent the Beast of Revelation. As much as this may have upset the
mayor, Linnaeus made his observations public and the mayor's dreams of selling the hydra for an enormous sum were ruined. Fearing his wrath, Linnaeus and Sohlberg had to leave Hamburg quickly.[50][51]

When Linnaeus reached Harderwijk, he began working toward a degree immediately; at the time, Harderwijk was known for awarding "instant" degrees after as little as a week.[52] First he handed in a thesis on the cause of malaria he had written in Sweden, which he then defended in a public debate. He is now known to have been wrong about the cause, not having a microscope good enough to see malarial parasites, which were spread by mosquitoes living in the stagnant water around the clay soils.[53]

The next step was to take an oral examination and to diagnose a patient. After less than two weeks, he took his degree and became a doctor, at the age of 28.[50][52] During the summer, Linnaeus met a friend from Uppsala, Peter Artedi. Before their departure from Uppsala, Artedi and Linnaeus had decided should one of them die, the survivor would finish the other's work. Ten weeks later, Artedi drowned in one of the canals of Amsterdam, and his unfinished manuscript on the classification of fish was left to Linnaeus to complete.[54][55]

Publishing of Lua error in package.lua at line 80: module 'Module:Exponential search' not found.

One of the first scientists Linnaeus met in the Netherlands was Johan Frederik Gronovius to whom Linnaeus showed one of the several manuscripts he had brought with him from Sweden. The manuscript described a new system for classifying plants. When Gronovius saw it, he was very impressed, and offered to help pay for the printing. With an additional monetary contribution by the Scottish doctor Isaac Lawson, the manuscript was published as Lua error in package.lua at line 80: module 'Module:Exponential search' not found. (1735).[56][57]

Linnaeus became acquainted with one of the most respected physicians and botanists in the Netherlands, Herman Boerhaave, who tried to convince Linnaeus to make a career there. Boerhaave offered him a journey to South Africa and America, but Linnaeus declined, stating he would not stand the heat. Instead, Boerhaave convinced Linnaeus that he should visit the botanist Johannes Burman. After his visit, Burman, impressed with his guest's knowledge, decided Linnaeus should stay with him during the winter. During his stay, Linnaeus helped Burman with his Lua error in package.lua at line 80: module 'Module:Exponential search' not found. Burman also helped Linnaeus with the books on which he was working: Lua error in package.lua at line 80: module 'Module:Exponential search' not found. and Lua error in package.lua at line 80: module 'Module:Exponential search' not found.[58]

George Clifford

In August, during Linnaeus' stay with Burman, he met George Clifford III, a director of the Dutch East India Company and the owner of a rich botanical garden at the estate of Hartekamp in Heemstede.
Clifford was very impressed with Linnaeus' ability to classify plants, and invited him to become his physician and superintendent of his garden. Linnaeus had already agreed to stay with Burman over the winter, and could thus not accept immediately. However, Clifford offered to compensate Burman by offering him a copy of Sir Hans Sloane's *Natural History of Jamaica*, a rare book, if he let Linnaeus stay with him, and Burman accepted.[59][60] On 24 September 1735, Linnaeus became the botanical curator and house physician at Hartekamp, free to buy any book or plant he wanted.

In July 1736, Linnaeus travelled to England, at Clifford's expense.[61] He went to London to visit Sir Hans Sloane, a collector of natural history, and to see his cabinet,[62] as well as to visit the Chelsea Physic Garden and its keeper, Philip Miller. He taught Miller about his new system of subdividing plants, as described in *Natural History of Jamaica*. Miller was impressed, and from then on started to arrange the garden according to Linnaeus' system.[63] Linnaeus also traveled to Oxford University to visit the botanist Johann Jacob Dillenius. He failed, however, to make Dillenius publicly accept his new classification system. He then returned to Hartekamp, bringing with him many specimens of rare plants.[64] The next year, he published *Linnaeus*, in which he described 935 genera of plants, and shortly thereafter he supplemented it with *Linnaeus*, with another sixty (sexaginta) genera.[65]

His work at Hartekamp led to another book, *Linnaeus*, a catalogue of the botanical holdings in the herbarium and botanical garden of Hartekamp. He wrote it in nine months (completed in July 1737), but it was not published until 1738.[58] It contains the first use of the name *Nepenthes*, which Linnaeus used to describe a genus of pitcher plants.[66][note 3]

Linnaeus stayed with Clifford at Hartekamp until 18 October 1737 (new style), when he left the house to return to Sweden. Illness and the kindness of Dutch friends obliged him to stay some months longer in Holland. In May 1738, he set out for Sweden again. On the way home, he stayed in Paris for about a month, visiting botanists such as Antoine de Jussieu. After his return, Linnaeus never left Sweden again.[67][68]

Return to Sweden

When Linnaeus returned to Sweden on 28 June 1738, he went to Falun, where he entered into an engagement to Sara Elisabeth Moræa. Three months later, he moved to Stockholm to find employment as a physician, and thus to make it possible to support a family.[69][70] Once again, Linnaeus found a patron; he became acquainted with Count Carl Gustav Tessin, who helped him get work as a physician at the Admiralty.[71][72] During this time in Stockholm, Linnaeus helped found the Royal Swedish Academy of Science; he became the first Praeses in the academy by drawing of lots.[73]

Because his finances had improved and were now sufficient to support a family, he received permission to marry his fiancée, Sara Elisabeth Moræa. Their wedding was held 26 June 1739. Seven months later, Sara gave birth to their first son, Carl. Two years later, a daughter, Elisabeth Christina,
was born, and the subsequent year Sara gave birth to Sara Magdalena, who died when 15 days old. Sara and Linnaeus would later have four other children: Lovisa, Sara Christina, Johannes and Sophia.\[69][74]

In May 1741, Linnaeus was appointed Professor of Medicine at Uppsala University, first with responsibility for medicine-related matters. Soon, he changed place with the other Professor of Medicine, Nils Rosén, and thus was responsible for the Botanical Garden (which he would thoroughly reconstruct and expand), botany and natural history, instead. In October that same year, his wife and nine-year-old son followed him to live in Uppsala.\[75]

Öland and Gotland

Ten days after he was appointed Professor, he undertook an expedition to the island provinces of Öland and Gotland with six students from the university, to look for plants useful in medicine. First, they travelled to Öland and stayed there until 21 June, when they sailed to Visby in Gotland. Linnaeus and the students stayed on Gotland for about a month, and then returned to Uppsala. During this expedition, they found 100 previously unrecorded plants. The observations from the expedition were later published in *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*, written in Swedish. Like *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*, it contained both zoological and botanical observations, as well as observations concerning the culture in Öland and Gotland.\[76][77]

During the summer of 1745, Linnaeus published two more books: *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* and *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*. *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* was a strictly botanical book, while *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* was zoological.\[69][78] Anders Celsius had created the temperature scale named after him in 1742. Celsius’ scale was inverted compared to today, the boiling point at 0 °C and freezing point at 100 °C. In 1745, Linnaeus inverted the scale to its present standard.\[79]

Västergötland

In the summer of 1746, Linnaeus was once again commissioned by the Government to carry out an expedition, this time to the Swedish province of Västergötland. He set out from Uppsala on 12 June and returned on 11 August. On the expedition his primary companion was Erik Gustaf Lidbeck, a student who had accompanied him on his previous journey. Linnaeus described his findings from the expedition in the book *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*, published the next year.\[76][80] After returning from the journey the Government decided Linnaeus should take on another expedition to the southernmost province Scania. This journey was postponed, as Linnaeus felt too busy.\[69]
In 1747, Linnaeus was given the title archiater, or chief physician, by the Swedish king Adolf Frederick—a mark of great respect.\[81\] The same year he was elected member of the Academy of Sciences in Berlin.\[82\]

### Scania

In the spring of 1749, Linnaeus could finally journey to Scania, again commissioned by the Government. With him he brought his student, Olof Söderberg. On the way to Scania, he made his last visit to his brothers and sisters in Stenbrohult since his father had died the previous year. The expedition was similar to the previous journeys in most aspects, but this time he was also ordered to find the best place to grow walnut and Swedish whitebeam trees; these trees were used by the military to make rifles. The journey was successful, and Linnaeus’ observations were published the next year in Lua error in package.lua at line 80: module 'Module:Exponential search' not found..\[83\][84]

### Rector of Uppsala University

In 1750, Linnaeus became rector of Uppsala University, starting a period where natural sciences were esteemed.\[69\] Perhaps the most important contribution he made during his time at Uppsala was to teach; many of his students travelled to various places in the world to collect botanical samples. Linnaeus called the best of these students his "apostles".\[85\] His lectures were normally very popular and were often held in the Botanical Garden. He tried to teach the students to think for themselves and not trust anybody, not even him. Even more popular than the lectures were the botanical excursions made every Saturday during summer, where Linnaeus and his students explored the flora and fauna in the vicinity of Uppsala.\[86\]

**Philosophia Botanica**

Linnaeus published *Philosophia Botanica* in 1751. The book contained a complete survey of the taxonomy system he had been using in his earlier works. It also contained information of how to keep a journal on travels and how to maintain a botanical garden.\[87\]

**Species Plantarum**

*Main article: Species Plantarum*

Linnaeus published *Species Plantarum*, the work which is now internationally accepted as the starting point of modern botanical nomenclature, in 1753.\[88\] The first volume was issued on 24 May, the second volume followed on 16 August of the same year.\[note 4\][90] The book contained 1,200 pages and
was published in two volumes; it described over 7,300 species. The same year the king dubbed him knight of the Order of the Polar Star, the first civilian in Sweden to become a knight in this order. He was then seldom seen not wearing the order.

### Ennoblement

Linnaeus felt Uppsala was too noisy and unhealthy, so he bought two farms in 1758: Hammarby and Sävja. The next year, he bought a neighbouring farm, Edeby. He spent the summers with his family at Hammarby; initially it only had a small one-storey house, but in 1762 a new, larger main building was added. In Hammarby, Linnaeus made a garden where he could grow plants that could not be grown in the Botanical Garden in Uppsala. He began constructing a museum on a hill behind Hammarby in 1766, where he moved his library and collection of plants. A fire that destroyed about one third of Uppsala and had threatened his residence there necessitated the move.

Since the initial release of *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* in 1735, the book had been expanded and reprinted several times; the tenth edition was released in 1758. This edition established itself as the starting point for zoological nomenclature, the equivalent of *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*

The Swedish king Adolf Frederick granted Linnaeus nobility in 1757, but he was not ennobled until 1761. With his ennoblement, he took the name Carl von Linné (Latinized as *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*), 'Linné' being a shortened and gallicised version of 'Linnæus', and the German title 'von' signifying his ennoblement. The noble family's coat of arms prominently features a twinflower, one of Linnaeus' favourite plants; it was given the scientific name *Linnaea borealis* in his honour by Gronovius. The shield in the coat of arms is divided into thirds: red, black and green for the three kingdoms of nature (animal, mineral and vegetable) in Linnaean classification; in the center is an egg "to denote Nature, which is continued and perpetuated in ovo." At the bottom is a phrase in Latin, borrowed from the Aeneid, which reads "FAMAM EXTENDERE FACTIS": we extend our fame by our deeds.

After his ennoblement, Linnaeus continued teaching and writing. His reputation had spread over the world, and he corresponded with many different people. For example, Catherine II of Russia sent him seeds from her country. He also corresponded with Giovanni Antonio Scopoli, "the Linnaeus of the Austrian Empire", who was a doctor and a botanist in Idrija, Duchy of Carniola (nowadays Slovenia). Scopoli communicated all of his research, findings, and descriptions (for example of the olm and the dormouse, two little animals hitherto unknown to Linnaeus). Linnaeus greatly respected him and showed great interest in his work. He named a solanaceous genus, *Scopolia*, the source of scopolamine, after him. Because of a great distance, they didn't ever meet.

### Final years

Linnaeus was relieved of his duties in the Royal Swedish Academy of Science in 1763, but continued his work there as usual for more than ten years after. He stepped down as rector at Uppsala University in December 1772, mostly due to his declining health.

Linnaeus' last years were troubled by illness. He had suffered from a disease called the Uppsala fever in 1764, but survived thanks to the care of Rosén. He developed sciatica in 1773, and the next year, he had a stroke which partially paralysed him. He suffered a second stroke in 1776, losing the use of
had a stroke which partially paralysed him. —— He suffered a second stroke in 1776, losing the use of his right side and leaving him bereft of his memory; while still able to admire his own writings, he could not recognize himself as their author.[106][107]

In December 1777, he had another stroke which greatly weakened him, and eventually led to his death on 10 January 1778 in Hammarby.[104][108] Despite his desire to be buried in Hammarby, he was interred in Uppsala Cathedral on 22 January.[109][110]

His library and collections were left to his widow Sara and their children. Joseph Banks, an English botanist, wanted to buy the collection, but his son Carl refused and moved the collection to Uppsala. However, in 1783 Carl died and Sara inherited the collection, having outlived both her husband and son. She tried to sell it to Banks, but he was no longer interested; instead an acquaintance of his agreed to buy the collection. The acquaintance was a 24-year-old medical student, James Edward Smith, who bought the whole collection: 14,000 plants, 3,198 insects, 1,564 shells, about 3,000 letters and 1,600 books. Smith founded the Linnean Society of London five years later.[110][111]

The von Linné name ended with his son Carl, who never married.[4] His other son, Johannes, had died aged 3.[112] There are over two hundred descendants of Linnaeus through two of his daughters.[4]

**Apostles**

*Main article: Apostles of Linnaeus*

During Linnaeus' time as Professor and Rector of Uppsala University, he taught many devoted students, 17 of whom he called "apostles". They were the most promising, most committed students, and all of them made botanical expeditions to various places in the world, often with his help. The amount of this help varied; sometimes he used his influence as Rector to grant his apostles a scholarship or a place on an expedition.[113] To most of the apostles he gave instructions of what to look for on their journeys. Abroad, the apostles collected and organised new plants, animals and minerals according to Linnaeus' system. Most of them also gave some of their collection to Linnaeus when their journey was finished.[114] Thanks to these students, the Linnaean system of taxonomy spread through the world without Linnaeus ever having to travel outside Sweden after his return from Holland.[115] The British botanist William T. Stearn notes without Linnaeus' new system, it would not have been possible for the apostles to collect and organise so many new specimens.[116] Many of the apostles died during their expeditions.

**Early expeditions**

Christopher Tärnström, the first apostle and a 43-year-old pastor with a wife and children, made his journey in 1746. He boarded a Swedish East India Company ship headed for China. Tärnström never reached his destination, dying of a tropical fever on Côn Sơn Island the same year. Tärnström's widow
blamed Linnaeus for making her children fatherless, causing Linnaeus to prefer sending out younger, unmarried students after Tärnström.[117] Six other apostles later died on their expeditions, including Pehr Forsskål and Pehr Löfling.[116]

Two years after Tärnström's expedition, Finnish-born Pehr Kalm set out as the second apostle to North America. There he spent two-and-a-half years studying the flora and fauna of Pennsylvania, New York, New Jersey and Canada. Linnaeus was overjoyed when Kalm returned, bringing back with him many pressed flowers and seeds. At least 90 of the 700 North American species described in *Species Plantarum* had been brought back by Kalm.[118]

**Cook expeditions and Japan**

Daniel Solander was living in Linnaeus' house during his time as a student in Uppsala. Linnaeus was very fond of him, promising Solander his oldest daughter's hand in marriage. On Linnaeus' recommendation, Solander travelled to England in 1760, where he met the English botanist Joseph Banks. With Banks, Solander joined James Cook on his expedition to Oceania on the *Endeavour* in 1768–71.[119][120] Solander was not the only apostle to journey with James Cook; Anders Sparrman followed on the *Resolution* in 1772–75 bound for, among other places, Oceania and South America. Sparrman made many other expeditions, one of them to South Africa.[121]

Perhaps the most famous and successful apostle was Carl Peter Thunberg, who embarked on a nine-year expedition in 1770. He stayed in South Africa for three years, then travelled to Japan. All foreigners in Japan were forced to stay on the island of Dejima outside Nagasaki, so it was thus hard for Thunberg to study the flora. He did, however, manage to persuade some of the translators to bring him different plants, and he also found plants in the gardens of Dejima. He returned to Sweden in 1779, one year after Linnaeus' death.[122]

**Major publications**

*Main article: Carl Linnaeus bibliography*

**Systema Naturae**

*Main article: Systema Naturae*

The first edition of *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* was printed in the Netherlands in 1735. It was a twelve-page work.[123] By the time it reached its 10th edition in 1758, it classified 4,400 species of animals and 7,700 species of plants. In it, the unwieldy names mostly used at the time, such as "*Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*", were supplemented with concise and now familiar "binomials", composed of the generic name, followed by a specific epithet – in the case given, *Physalis angulata*. These binomials could serve as a label to refer to the species. Higher taxa were constructed and arranged in a simple and orderly manner. Although the system, now known as binomial nomenclature, was partially developed by the Bauhin brothers (see Gaspard Bauhin and
Johann Bauhin) almost 200 years earlier,[124] Linnaeus was the first to use it consistently throughout the work, including in monospecific genera, and may be said to have popularised it within the scientific community.

After the decline in Linnaeus' health in the early 1770s, publication of editions of *Systema Naturae* went in two different directions. Another Swedish scientist, Johan Andreas Murray issued the *Regnum Vegetabile* section separately in 1774 as the *Systema Vegetabilium*, rather confusingly labelled the 13th edition.[125] Meanwhile a 13th edition of the entire *Systema* appeared in parts between 1788-1793. It was as the *Systema Vegetabilium*, that Linnaeus' work became widely known in England following translation from the Latin by the Lichfield Botanical Society, as *A System of Vegetables* (1783–1785).[126]

---

**Lua error in package.lua at line 80: module 'Module:Exponential search' not found.**

Main article: *Species Plantarum*

(or, more fully, *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*) was first published in 1753, as a two-volume work. Its prime importance is perhaps that it is the primary starting point of plant nomenclature as it exists today.[88]

**Lua error in package.lua at line 80: module 'Module:Exponential search' not found.**

Main article: *Genera Plantarum*

*Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* was first published in 1737, delineating plant genera. Around 10 editions were published, not all of them by Linnaeus himself; the most important is the 1754 fifth edition.[127] In it Linnaeus divided the plant Kingdom into 24 classes. One, Cryptogamia, included all the plants with concealed reproductive parts (algae, fungi, mosses and liverworts and ferns).[128]

**Lua error in package.lua at line 80: module 'Module:Exponential search' not found.**

Main article: *Philosophia Botanica*

*Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* (1751) was a summary of Linnaeus' thinking on plant classification and nomenclature, and an elaboration of the work he had previously published in *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* (1736) and *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* (1737). Other publications forming part of his plan to reform the foundations of botany include his *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* and *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.*: all were printed in Holland (as well as *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* (1737) and *Lua error in package.lua at line 80: module 'Module:Exponential search' not found.* (1735)), the *Philosophia* being simultaneously released in Stockholm.[129]
Linnaean collections

At the end of his lifetime the Linnean collection in Uppsala was considered one of the finest collections of natural history objects in Sweden. Next to his own collection he had also built up a museum for the university of Uppsala, which was supplied by material donated by Carl Gyllenborg (in 1744–1745), crown-prince Adolf Fredrik (in 1745), Erik Petreus (in 1746), Claes Grill (in 1746), Magnus Lagerström (in 1748 and 1750) and Jonas Alströmer (in 1749). The relation between the museum and the private collection was not formalized and the steady flow of material from Linnean pupils were incorporated to the private collection rather than to the museum. Linnaeus felt his work was reflecting the harmony of nature and he said in 1754 'the earth is then nothing else but a museum of the all-wise creator's masterpieces, divided into three chambers'. He had turned his own estate into a microcosm of that 'world museum'.

In April 1766 parts of the town were destroyed by a fire and the Linnean private collection was subsequently moved to a barn outside the town, and shortly afterwards to a single-room stone building close to his countryhouse at Hammarby near Uppsala. This resulted in a physical separation between the two collections, the museum collection remained in the botanical garden of the university. Some material which needed special care (alcohol specimens) or ample storage space was moved from the private collection to the museum.

In Hammarby the Linnean private collections suffered seriously from damp and the depredations by mice and insects. Carl von Linné’s son (Carl Linnaeus) inherited the collections in 1778 and retained them until his own death in 1783. Shortly after Carl von Linné’s death his son confirmed that mice had caused "horrible damage" to the plants and that also moths and mould had caused considerable damage. He tried to rescue them from the neglect they had suffered during his father's later years, and also added further specimens. This last activity however reduced rather than augmented the scientific value of the original material.

In 1784 the botanist James Edward Smith purchased nearly all of the Linnean private scientific effects from the widow and daughter of Carl Linnaeus and transferred them to London. Not all material in Linné's private collection was transported to England. Thirty-three fish specimens preserved in alcohol were not sent and were later lost.

In London Smith tended to neglect the zoological parts of the collection, he added some specimens and also gave some specimens away. Over the following centuries the Linnean collection in London suffered enormously at the hands of scientists who studied the collection, and in the process disturbed the original arrangement and labels, added specimens that did not belong to the original series and withdrew precious original type material.

Much material which had been intensively studied by Linné in his scientific career belonged to the collection of Queen Lovisa Ulrika (1720–1782) (in the Linnean publications referred to as "Museum Ludovicae Ulricae" or "M. L. U."). This collection was donated by his grandson King Gustav IV Adolf (1778–1837) to the museum in Uppsala in 1804. Another important collection in this respect was that of her husband King Adolf Fredrik (1710–1771) (in the Linnean sources known as "Museum Adolphi
Friderici" or "Mus. Ad. Fr."). The wet parts (alcohol collection) of which were later donated to the Royal Swedish Academy of Sciences, and is today housed in the Swedish Museum of Natural History at Stockholm. The dry material was transferred to Uppsala.[130]

**Linnaean taxonomy**

*Main article: Linnaean taxonomy*

The establishment of universally accepted conventions for the naming of organisms was Linnaeus' main contribution to taxonomy—his work marks the starting point of consistent use of binomial nomenclature.[135] During the 18th century expansion of natural history knowledge, Linnaeus also developed what became known as the *Linnaean taxonomy*; the system of scientific classification now widely used in the biological sciences.

The Linnaean system classified nature within a nested hierarchy, starting with three kingdoms. Kingdoms were divided into classes and they, in turn, into orders, and thence into genera (*singular*: genus), which were divided into Species (*singular*: species).[136] Below the rank of species he sometimes recognized taxa of a lower (unnamed) rank; these have since acquired standardised names such as *variety* in botany and *subspecies* in zoology. Modern taxonomy includes a rank of family between order and genus and a rank of phylum between kingdom and class that were not present in Linnaeus' original system.[137]

Linnaeus' groupings were based upon shared physical characteristics, and not simply upon differences.[137] Of his higher groupings, only those for animals are still in use, and the groupings themselves have been significantly changed since their conception, as have the principles behind them. Nevertheless, Linnaeus is credited with establishing the idea of a hierarchical structure of classification which is based upon observable characteristics and intended to reflect natural relationships.[135][138] While the underlying details concerning what are considered to be scientifically valid "observable characteristics" have changed with expanding knowledge (for example, DNA sequencing, unavailable in Linnaeus' time, has proven to be a tool of considerable utility for classifying living organisms and establishing their evolutionary relationships), the fundamental principle remains sound.

**Influences and economic beliefs**

Linnaeus' applied science was inspired not only by the instrumental utilitarianism general to the early Enlightenment, but also by his adherence to the older economic doctrine of Cameralism.[139] Additionally, Linnaeus was a state interventionist. He supported tariffs, levies, export bounties, quotas, embargoes, navigation acts, subsidized investment capital, ceilings on wages, cash grants, state-licensed producer monopolies, and cartels.[140]

**Views on mankind**
According to German biologist Ernst Haeckel, the question of man’s origin began with Linnaeus. He helped future research in the natural history of man by describing humans just as he described any other plant or animal.\[141\]

**Anthropomorpha**

Linnaeus classified humans among the primates (as they were later called) beginning with the first edition of *Lu[\(\text{a error in package.lua at line 80: module 'Module:Exponential search' not found.}\])*. During his time at Hartekamp, he had the opportunity to examine several monkeys and noted similarities between them and man.\[85\] He pointed out both species basically have the same anatomy; except for speech, he found no other differences.\[142\]\[note 5\] Thus he placed man and monkeys under the same category, *Anthropomorpha*, meaning "manlike."\[143\] This classification received criticism from other biologists such as Johan Gottschalk Wallerius, Jacob Theodor Klein and Johann Georg Gmelin on the ground that it is illogical to describe a human as 'like a man'.\[144\] In a letter to Gmelin from 1747, Linnaeus replied:\[145\]\[note 6\]

*It does not please [you] that I've placed Man among the Anthropomorpha, perhaps because of the term 'with human form';\[note 7\] but man learns to know himself. Let's not quibble over words. It will be the same to me whatever name we apply. But I seek from you and from the whole world a generic difference between man and simian that [follows] from the principles of Natural History;\[note 8\] I absolutely know of none. If only someone might tell me a single one! If I would have called man a simian or vice versa, I would have brought together all the theologians against me. Perhaps I ought to have by virtue of the law of the discipline.*

The theological concerns were twofold: first, putting man at the same level as monkeys or apes would lower the spiritually higher position that man was assumed to have in the great chain of being, and second, because the Bible says man was created in the image of God\[146\] (theomorphism), if monkeys/apes and humans were not distinctly and separately designed, that would mean monkeys and apes were created in the image of God as well. This was something many could not accept.\[147\] The conflict between world views that was caused by asserting man was a type of animal would simmer for a century until the much greater, and still ongoing, creation–evolution controversy began in earnest with the publication of *On the Origin of Species* by Charles Darwin in 1859.

After such criticism, Linnaeus felt he needed to explain himself more clearly. The 10th edition of *Lu[\(\text{a error in package.lua at line 80: module 'Module:Exponential search' not found.}\])* introduced new terms, including *Mammalia* and *Primates*, the latter of which would replace *Anthropomorpha*\[148\] as well as giving humans the full binomial *Homo sapiens*\[149\]. The new
Anthropomorpha—as well as giving humans the full binomial Homo sapiens.—The new classification received less criticism, but many natural historians still believed he had demoted humans from their former place to rule over nature, not be a part of it. Linnaeus believed that man biologically belongs to the animal kingdom and had to be included in it.\textsuperscript{[150]} In his book \textit{Linnaeus tried to debunk some of these creatures, as he had with the hydra; regarding the purported remains of dragons, Linnaeus wrote that they were either derived from lizards or rays.\textsuperscript{[158]} For \textit{Homo troglodytes} he asked the Swedish East India Company to search for one, but they did not find any signs of its existence.\textsuperscript{[159]} Homo lar has since been reclassified as \textit{Hylobates lar}, the lar gibbon.\textsuperscript{[160]}

\textbf{Strange people in distant lands}

Linnaeus added a second species to the genus \textit{Homo} in the first edition of \textit{Linnaeus subdivided the human species into four varieties based on continent and skin colour: "Europæus albus" (white European), "Americanus rubescens" (red American), "Asiaticus fuscus" (brown Asian) and "Africanus Niger" (black African). In the tenth edition of Systema Naturae he further detailed stereotypical characteristics for each variety, based on the concept of the four temperaments from classical antiquity, and changed the description of Asians' skin tone to "luridus" (yellow).\textsuperscript{[161]}\textsuperscript{[162]}\textsuperscript{[163]}\textsuperscript{[164]}\textsuperscript{[165]}} Additionally, Linnaeus created a wastebasket taxon "monstrosus" for "wild and monstrous humans, unknown groups, and more or less abnormal people."\textsuperscript{[166]}

\textit{Commemoration}

\textit{Main article: Commemoration of Carl Linnaeus}
Anniversaries of Linnaeus' birth, especially in centennial years, have been marked by major celebrations. Linnaeus has appeared on numerous Swedish postage stamps and banknotes. There are numerous statues of Linnaeus in countries around the world. The Linnean Society of London has awarded the Linnean Medal for excellence in botany or zoology since 1888. Following approval by the Parliament of Sweden, Växjö University and Kalmar College merged on 1 January 2010 to become Linnaeus University. Other things named after Linnaeus include the twinflower genus Linnaea, the crater Linné on the Earth’s moon and the cobalt sulfide mineral Linnaeite.

Commentary on Linnaeus

Andrew Dickson White wrote in *A History of the Warfare of Science with Theology in Christendom* (1896):

> Linnaeus ... was the most eminent naturalist of his time, a wide observer, a close thinker; but the atmosphere in which he lived and moved and had his being was saturated with biblical theology, and this permeated all his thinking. ... Toward the end of his life he timidly advanced the hypothesis that all the species of one genus constituted at the creation one species; and from the last edition of his *Systema Naturæ* he quietly left out the strongly orthodox statement of the fixity of each species, which he had insisted upon in his earlier works. ... warnings came speedily both from the Catholic and Protestant sides.

The mathematical PageRank algorithm, applied to 24 multilingual Wikipedia editions in 2014, places Carl Linnaeus at the first position among top 100 historical figures.

Footnotes

1. ^a b Carl Linnaeus was born in 1707 on 13 May (Swedish Style) or 23 May according to the modern calendar. According to the Julian calendar he was born 12 May. (Blunt 2004, p. 12)
2. [1] (http://www.nhm.ac.uk/hosted-sites/iczn/code/) ICZN Chapter 16, Article 72.4.1.1 – "For a nominal species or subspecies established before 2000, any evidence, published or unpublished, may be taken into account to determine what specimens constitute the type series." and Article 73.1.2 – "If the nominal species-group taxon is based on a single specimen, either so stated or implied in the original publication, that specimen is the holotype fixed by monotypy (see Recommendation 73F). If the taxon was established before 2000 evidence derived from outside the work itself may be taken into account [Art. 72.4.1.1] to help identify the specimen."

3. "If this is not Helen's *Nepenthes*, it certainly will be for all botanists. What botanist would not be filled with admiration if, after a long journey, he should find this wonderful plant. In his astonishment past ills would be forgotten when beholding this admirable work of the Creator!" (translated from Latin by Harry Veitch)

4. The date of issue of both volumes was later, for practical purposes, arbitrarily set on 1 May, see Stearn, W.T. (1957), The preparation of the *Species Plantarum* and the introduction of binomial nomenclature, in: *Species Plantarum*, A Facsimile of the first edition, London, Ray Society: 72 and ICN (*Melbourne Code*)[89] Art. 13.4 Note 1: "The two volumes of Linnaeus' *Species plantarum*, ed. 1 (1753), which appeared in May and August, 1753, respectively, are treated as having been published simultaneously on 1 May 1753."

5. Frängsmyr et al. (1983), p. 167, quotes Linnaeus explaining the real difference would necessarily be absent from his classification system, as it was not a morphological characteristic: "I well know what a splendidly great difference there is [between] a man and a bestia [literally, "beast"; that is, a non-human animal] when I look at them from a point of view of morality. Man is the animal which the Creator has seen fit to honor with such a magnificent mind and has condescended to adopt as his favorite and for which he has prepared a nobler life". See also google.com (http://books.google.com/books?id=wlkOAAAQAQAAJ&pg=PA179#v=onepage&q&f=false) in which Linnaeus cites the significant capacity to reason as the distinguishing characteristic of humans.

7. "antropomorphon" [sic]

8. Others who followed were more inclined to give humans a special place in classification; Johann Friedrich Blumenbach in the first edition of his *Manual of Natural History* (1779), proposed that the primates be divided into the Quadruped (four-handed, i.e. apes and monkeys) and Bimana (two-handed, i.e. humans). This distinction was taken up by other naturalists, most notably Georges Cuvier. Some elevated the distinction to the level of order. However, the many affinities between humans and other primates – and especially the great apes – made it clear that the distinction made no scientific sense. Charles Darwin wrote, in *The Descent of Man* in 1871:

The greater number of naturalists who have taken into consideration the whole structure of man, including his mental faculties, have followed Blumenbach and Cuvier, and have placed man in a separate Order, under the title of the Bimana, and therefore on an equality with the orders of the Quadruped, Carnivora, etc. Recently many of our best naturalists have recurred to the view first propounded by Linnaeus, so remarkable for his sagacity, and have placed man in the same Order with the Quadruped, under the title of the Primates. The justice of this conclusion will be admitted: for in the first place, we must bear in mind the comparative insignificance for classification of the great development of the brain in man, and that the strongly marked differences between the skulls of man and the Quadruped (lately insisted upon by Bischoff, Aeby, and others) apparently follow from their differently developed brains. In the second place, we must remember that nearly all the other and more
important differences between man and the Quadrumana are manifestly adaptive in their nature, and relate chiefly to the erect position of man; such as the structure of his hand, foot, and pelvis, the curvature of his spine, and the position of his head.

9. Linnaeus is translated, writing that the satyrus is "hairy, bearded, with a manlike body, gesticulating much, very fallacious, is a species of monkey, if ever one has been seen."
